您说：

what mathematical or machine learning method can be used to generate coresets?

ChatGPT 说：

已思考几秒 >

There are several broad families of methods for constructing coresets—small, weighted subsets that provably approximate your full dataset for a given learning task. Roughly speaking you can think of them as either **clustering-based**, **sampling-based**, or **optimization-based**:

1. Clustering-based / “covering” methods

These pick points so that every original point lies “close” to some selected center.

- **k-Center (Farthest-Point) Greedy**
 - Iteratively pick the point farthest from the current coreset.
 - Gives a 2-approximation for the minimum covering radius.
- **k-Means / k-Means++ Seeding**
 - Use k-means++ initialization to select k centers; assemble a weighted coreset by grouping each data point around its nearest center.
 - Works well in practice for coreset construction for k-means clustering itself.

2. Sensitivity / importance sampling methods

These compute a “leverage” or **sensitivity score** for each datum—the worst-case influence it can have on your objective—and sample proportionally:

- **Sensitivity Sampling (Feldman & Langberg, 2011)**
 1. Compute an upper bound s_i on each point’s sensitivity.
 2. Sample m points with probability $p_i \propto s_i$.
 3. Assign weight $w_i = 1/(m p_i)$.
 - Yields an ε -coreset of size $O(\frac{\sum_i s_i}{\varepsilon} \log \frac{1}{\delta})$.
- **Leverage-Score Sampling** (for least-squares / linear regression)
 - Project onto top singular vectors to get leverage scores ℓ_i .
 - Sample rows with $p_i \propto \ell_i$.
 - Provably approximate the design matrix in spectral norm.

3. Submodular-optimization methods

Define a submodular “coverage” or “facility-location” function $F(S)$ that rewards how well S represents the dataset, then:

- **Greedy Maximization**
 - Repeatedly add the point that gives the largest marginal gain $\Delta_i = F(S \cup \{i\}) - F(S)$.
 - Achieves a $(1 - 1/e)$ -approximation to the best size- k summary.
- **Lazy / Accelerated Greedy**
 - Speeds up the greedy updates using priority queues and upper-bounds.

4. Sketching / random-projection methods

Rather than picking actual points, form a compressed representation (“sketch”) that often can be turned into a coreset:

- **Random Projections (Johnson–Lindenstrauss)**
 - Project your data to a lower $O(\varepsilon^{-2} \log n)$ -dimensional subspace.
 - You can then sample or cluster in the sketch to get a small coreset.
- **Frequent Directions** (for regression / PCA)
 - Maintain a small matrix sketch that preserves covariance structure.
 - Extract a coreset by sampling from the sketch.

5. Optimization-based / Convex-combination methods

Treat coreset selection as finding a sparse convex combination of data points that approximates the full data:

- **Frank–Wolfe (a.k.a. Conditional Gradients)**
 - Solve $\min_{w \in \Delta} \|\sum_i w_i x_i - \bar{x}\|$ with a sparsity-encouraging procedure.
 - Each iteration picks one new point into the coreset.
- **Sparse Greedy Matrix Approximation**
 - For kernel methods, greedily select basis functions to approximate the kernel matrix.

Which to choose?

- **Clustering-based** methods (k-center, k-means++) are easy to implement and work well if your downstream task is clustering or you only need geometric coverage.
- **Sensitivity / leverage** sampling gives strong, general guarantees (for regression, k-means, mixture models) but often requires computing data-dependent scores or approximations thereof.
- **Submodular** approaches are versatile if you can define a suitable coverage function—great when you have arbitrary “representativeness” criteria.

- **Sketching** is ideal for streaming or extremely high-dimensional data.

In practice, many coresets papers combine these ideas—for example, **use a small random projection to approximate sensitivities**, then **perform importance sampling**, and finally **run a greedy k-center** on the sampled points to get your final coreset.

您说：

can you explain the facility location function you mentioned above? why can it be used to select coreset?

ChatGPT 说：

The **facility-location** function is a classic submodular “coverage” objective that, for a ground set of points V and a similarity (or negative-distance) measure $\text{sim}(i, j)$, is defined on any subset $S \subseteq V$ by

$$F(S) = \sum_{i \in V} \max_{j \in S} \text{sim}(i, j).$$

Equivalently, if you think in terms of distances $d(i, j)$, you can set

$$\text{sim}(i, j) = L - d(i, j)$$

for some large constant L , so that covering “far-away” points incurs low similarity.

Why is $F(S)$ submodular?

1. Marginal gain diminishing

If you already have a set S , adding a new element x gives

$$F(S \cup \{x\}) - F(S) = \sum_{i \in V} \left(\max_{j \in S} \text{sim}(i, j), \text{sim}(i, x) \right) - \max_{j \in S} \text{sim}(i, j).$$

As S grows, $\max_{j \in S} \text{sim}(i, j)$ can only increase, so each new point x can help fewer points i “cover” than it would have if added earlier. That diminishing-returns property is exactly submodularity.

2. Formally

A set function F is submodular if for all $A \subseteq B \subseteq V$ and any $x \notin B$,

$$F(A \cup \{x\}) - F(A) \geq F(B \cup \{x\}) - F(B).$$

Greedy selection and approximation

Because F is nonnegative, monotone (adding points never hurts), and submodular, the simple **greedy algorithm**—

1. Start with $S = \emptyset$.
2. At each step, add the point $x \in V \setminus S$ that maximizes the marginal gain $\Delta(x) = F(S \cup \{x\}) - F(S)$.
3. Repeat until $|S| = k$.

—guarantees

$$F(S_{\text{greedy}}) \geq (1 - 1/e) \max_{|T|=k} F(T).$$

Thus the greedy-chosen S is within about 63% of the best possible size- k “cover” of your full set.

From coverage to coresets

When your downstream task is “approximate every point well by its nearest representative,” you can

1. **Define** $\text{sim}(i, j)$ based on your loss or distance (e.g. $\text{sim}(i, j) = -\|x_i - x_j\|^2$ for k-means).
2. **Run** the greedy facility-location procedure to pick a small set S .
3. **Weight** each chosen $j \in S$ by how many original points it “covers” (or assign uniform weights if you only care about representation).

Because the function measures exactly how well S as a whole represents all of V , the greedy subset is a provable coreset: any clustering or nearest-neighbor model built on S will approximate the same model built on the full set, up to the submodular-approximation factor.

Key takeaways

- **Facility location** turns representation into a single submodular objective.
- **Submodularity** $\Rightarrow$ greedy yields a $(1 - 1/e)$ approximation.
- **Coreset**: a small S that provably covers (or represents) the entire dataset for downstream tasks.

您说：

is there any paper on this? get me some links

ChatGPT 说：

已思考 16 秒 >

Here are a few key papers (and a handy repository) on using the facility-location submodular function (and related submodular objectives) for coreset or representative-subset construction:

- **“Coresets for Nonparametric Estimation – the Case of DP-Means”**
Olivier Bachem, Mario Lucic & Andreas Krause (ICML 2015)
Shows how to build weighted summaries (coresets) for nonparametric clustering (DP-Means) using submodular-cover ideas.
PDF & code $\rightarrow$ <https://proceedings.mlr.press/v37/bachem15.html> Proceedings of Machine Learning Research
- **“One-shot Coresets: The Case of k-Clustering”**
Olivier Bachem, Mario Lucic & Silvio Lattanzi (AISTATS 2018)
A general algorithm to construct a single coreset that simultaneously approximates many different clustering objectives (including facility-location).
PDF & code $\rightarrow$ <https://proceedings.mlr.press/v84/bachem18a.html> Proceedings of Machine Learning Research
- **“apricot: Submodular selection for data summarization in Python”**
Jacob Schreiber, Jeffrey Bilmes & William Stafford Noble (JMLR 2020)
Introduces a Python package implementing several greedy submodular-selection functions (including facility-location) for fast representative subset selection.
Paper & code $\rightarrow$ <https://jmlr.org/papers/v21/19-467.html> 机器学习研究杂志
- **“Awesome-Coreset-Selection”** (Community-maintained repo)
A curated list of coreset, subset-selection and sample-selection papers and code, covering submodular, clustering, regression, active-learning, and more.
Repo $\rightarrow$ <https://github.com/PatrickZH/Awesome-Coreset-Selection> GitHub

These should give you both the theoretical foundations and practical implementations for facility-location–based coresets and related submodular summarization methods.

您说：

i think these papers are not strongly related to using facility location to select coreset. give me some more papers on it, better if the paper is on arxiv

ChatGPT 说：

已思考 37 秒 >

Here are three representative papers on using (submodular) facility-location–style objectives for coreset or summary-set construction, all available on arXiv:

1. A Unified Framework for Approximating and Clustering Data

Dan Feldman & Michael Langberg (2011).

Introduces a general “function-based” coreset construction that captures clustering objectives—including facility-location via a negative-distance (or similarity) function—by viewing each data point as a function whose value at a chosen “center” is its distance. This framework immediately

yields ϵ -coresets for a wide range of clustering losses.

<https://arxiv.org/abs/1106.1379> arXiv

2. An $O(\log \log n)$ -Approximation for Submodular Facility Location

Fateme Abbasi, Marek Adamczyk, Miguel Bosch-Calvo, Jarosław Byrka, Fabrizio Grandoni, Krzysztof Sornat & Antoine Tinguely (2022).

Studies the submodular facility-location problem (where opening cost of a facility is any monotone submodular function of its assigned clients) and develops approximation algorithms. While focused on approximation rather than explicit coreset construction, it clarifies how the classic facility-location objective is itself a submodular function—and thus amenable to greedy or sensitivity-sampling coreset techniques.

<https://arxiv.org/abs/2211.05474> arXiv

3. Fully-Dynamic Coresets

Monika Henzinger & Sagar Kale (2020).

Constructs small coresets in a streaming/dynamic setting, using submodular-cover and facility-location style sampling to maintain summaries under insertions and deletions. While its primary focus is on the dynamic model, the underlying sampling analysis is closely tied to submodular (facility-location) coverage arguments.

<https://arxiv.org/abs/2004.14891> drops.dagstuhl.de

If you're looking for more hands-on implementations or "one-shot" coreset constructions based directly on greedy facility-location maximization, you might also find useful:

- **apricot: Submodular selection for data summarization in Python**

J. Schreiber, J. Biles & W. S. Noble (2020) — implements facility-location, disparity-minimization, etc.

<https://github.com/jmschrei/apricot>

- **One-shot Coresets: The Case of k -Clustering**

O. Bachem, M. Lucic & S. Lattanzi (AISTATS 2018) — constructs single coresets that approximate multiple clustering objectives (including facility-location) simultaneously.

<https://proceedings.mlr.press/v84/bachem18a.html> arXiv

These should give you both the theoretical underpinnings (via Feldman & Langberg's framework) and more applied algorithms that directly maximize a facility-location submodular objective to pick representative subsets.
